[2]LVMT (UMR-T 9403 IFSTTAR)

January 26th 2016

Achieved Work (by projects)

- Biblio/Meetings/Organisation [0.7w]
- Conference [0.7w]
- Reading Records (*Synergetics* [Sanders, 1992]) [0.2w]
- Monitorat [1,3w]
- Cybergeo Project [1w]
- Correlated Synthetic data [3w]
- Theory construction (communication JIG) [0.2w]
- BP Case Study / Spatial Econometrics [0,3w]

Context

[Introduction at Rochebrune] : imagine a model of simulation describing skiers/ snowboarders relations, measures to improve situation ? NO conclusion without model exploration, including sensitivity to ressort station spatial configuration, or to population structure, even at second order $\rightarrow$ *Necessity in that case (among others) to generate synthetic data controlled at second order.*

Def. : *Synthetic Data* are output of generative models (and possibly inputs of models using them).

Methodology used in various fields, e.g. therapeutic evaluation [Abadie et al., 20 territorial systems analysis [Moeckel et al., 2003, Pritchard and Miller, 2009], machine learning [Bolón-Canedo et al., 2013] or bio-informatics [Van den Bulcke

Few examples at the second order : specific examples as [Ye, 2011] for discrete choices ; methods that can be interpreted this way : generation of complex networks [Newman, 2003].

Generic Method

$\vec{X}_I$ multidimensional stochastic process, $\mathbf{X} = (X_{i,j})$ realizations.

Aim : Generate a statistical population $\tilde{\mathbf{X}} = \tilde{X}_{i,j}$ such that:

1. proximity to data : given a precision ε and an indicator f, $\|f(\mathbf{X}) - f(\tilde{\mathbf{X}})\| < \varepsilon$
2. control of the estimated correlation structure : $\hat{\text{Var}}\left[(\tilde{X}_i)\right] = \Sigma R$ with R fixed.

Geographical data : Context

- In geography, generation of synthetic populations for agent-based models [Pritchard and Miller, 2009].
- Generation of spatial synthetic configuration not used (Geo. Weighted Regression [Brunsdon et al., 1998] can be interpreted this way) ; however crucial for abstract models [Schmitt, 2014]
- [Cottineau et al., 2015] recently proposed to estimate the sensitivity of spatial models of simulation to initial configuration (application to Schelling model).
- Case study : city-transportation interactions, complex to understood quantitatively [Offner, 1993, Bretagnolle, 2009] $\rightarrow$ simple model of population density and transportation network morphogenesis.

Model

Simple coupling between

- Iterative generation of a density grid by preferential attachment/diffusion [Raimbault, 2016] calibrated on morphological objectives on european density grid.

- Heuristic network generation conditional to density :
  - Distribution of a fixed number of centers preferentially following density
  - Deterministic percolation between closest neighbors
  - Breaking of interaction potentials

$$V_{ij}(d) = \left[(1-k_h) + k_h \cdot \left(\frac{P_i P_j}{P^2}\right)^\gamma\right] \cdot \exp\left(-\frac{d}{r_g(1+d/d_0)}\right)$$

  for a fixed number of couples N_L such that $V_{ij}(d_N)/V_{ij}(d_{ij})$ is minimal among $K \cdot N_L$ strongest euclidian potentials ($K = 5$ fixed)
  - Planarization

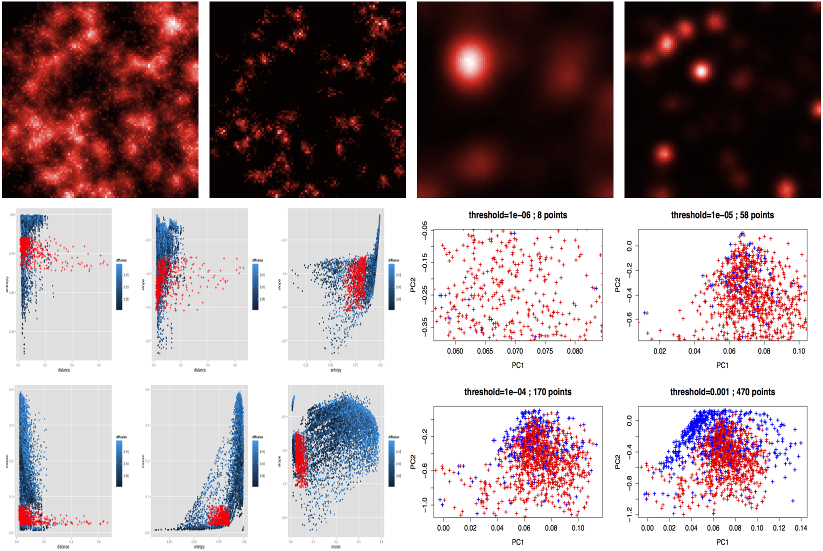
Indicators : morphology [Le Néchet, 2015] (Moran, mean distance, entropy, hierarchy) and network (centrality, mean width, speed, diameter).

Implementation and Exploration

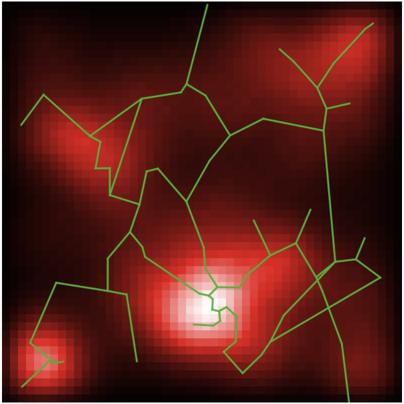
→ Formal and Operational coupling : modular implementation (`scala/NetLog`
encapsulated by `OpenMole` [Reuillon et al., 2013]

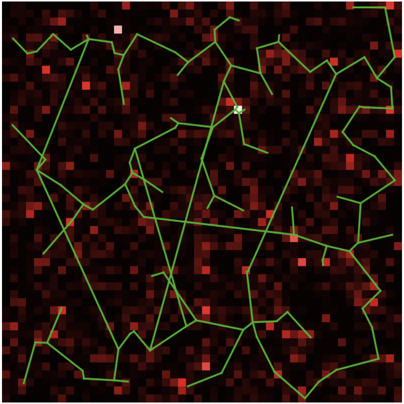
→ Exploration by intensive computation on grid via `OpenMole` : calibration of density model alone ($\sim 1.5 \cdot 10^6$ runs) ; brutal exploration by LHS sampling for feasible correlations ($\sim 5 \cdot 10^4$ runs)

Results : Density Model alone

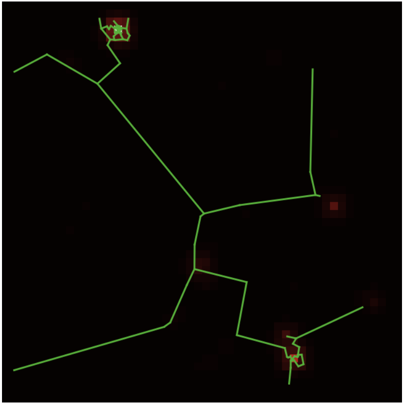


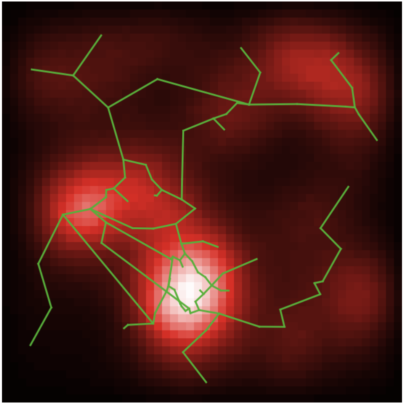
Results : examples of configurations



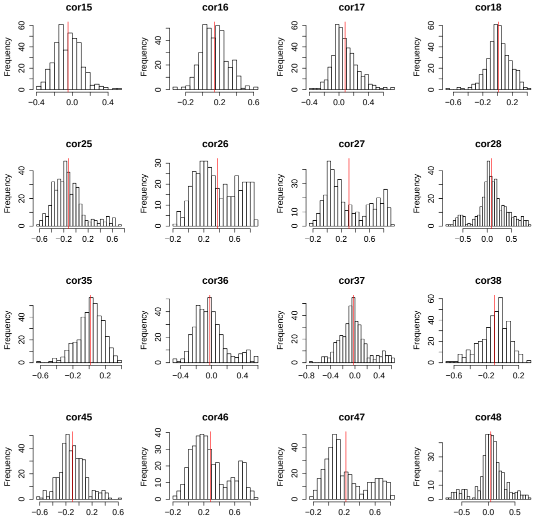


Results : examples of configurations



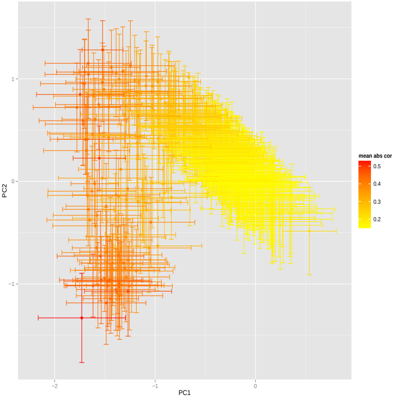


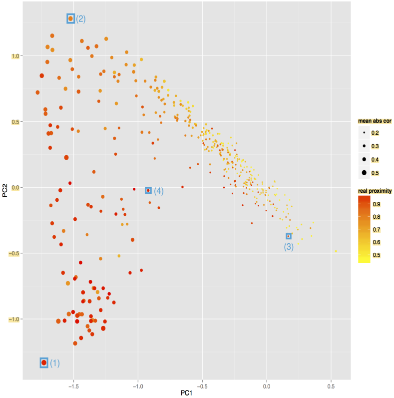
Results : cross-correlations



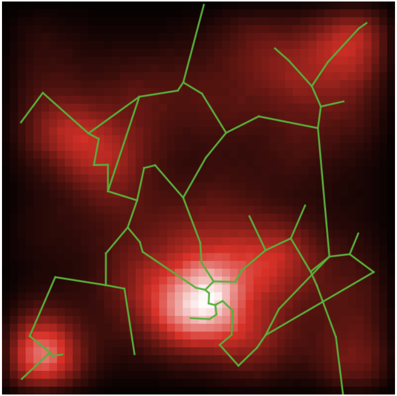
Results : feasible correlations

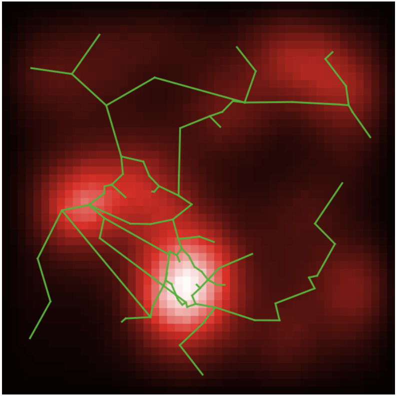
Mean matrices in a principal plan





Results : exemples of correlations





$\rho[\bar{d}, \bar{c}] \simeq 0.34$ $\rho[\bar{d}, \bar{c}] \simeq -0.41$

$\rightarrow$ *gravity hierarchy more important in (1)* $\gamma = 3.9, k_h = 0.7$ *against* $\gamma = 1.07, k_h = 0.25$ *for (2)*

Applications

1. Calibration of the coupled model, street network data (edge effects!)
   → generation of correlated synthetic data corresponding to a given urban system
   → intrinsic correlations to be compared to estimated correlations between different states : non-ergodicity of urban systems [Pumain, 2012]).

2. Dynamical correlations in a strongly coupled model / spatio-temporal correlations in a strong spatial coupling.

Case study : Context

Database by Florent : main road network (route 120) in extended *Bassin Parisien* with opening dates for highways ; census data : population and employment of *communes* at dates

Formalisation : Dynamic transportation network $n(\vec{x},t)$ within a dynamic territorial landscape $\vec{T}(\vec{x},t)$, which components are population $p(\vec{x},t)$ and employments $e(\vec{x},t)$, discretized in space and in time, i.e. the spatial field $\vec{T}$ is summarized by $\mathbf{T} = \left(\vec{T}(\vec{x}_i, t_j^{(T)})\right)_{i,j}$ with $1 \leq i \leq N$ and $1 \leq j \leq T$.

On Accessibility

Is the notion of accessibility crucial for statistical analysis ?

Weibull has proposed an axiomatic approach to accessibility [Weibull, 1976], deriving a canonical decomposition for any *attraction-accessibility* function $A(a,d)$, assuming expected thematic axioms among others technical ones that are :

1. A is invariant regarding the order of the configuration
2. A decrease with distance at fixed attraction and increase with attraction at fixed distance
3. A is invariant when adding null attractions and constant configurations

Then A verifies these *iff* it is of the form

$$A\left[(a_i,d_i)\right]=T\left(\sum_i z(d_i,a_i)\right)$$

where T is increasing with null origin, z is a *distance substitution function* (i.e. verifying axiom 2) and $\circ$

$\rightarrow$ *Well suited matrices of autocorrelation should capture accessibility in regressions.*

Statistical Analysis

Large set of analysis to be tested (non exhaustive) :

- On data :
  - Multivariate linear models
  - Autocorrelated univariate models
  - Autocorrelated multivariate models

- On data returns :
  - Granger causality tests : [Xie and Levinson, 2009] use Granger causality to link transit with land-use changes.
  - Autoregressive multivariate models
  - Autoregressive autocorrelated multivariate models

P. Bourgine framework for Complex Adaptive Systems

Bourgine has recently developed to represent Complex Adaptive Systems as Hidden Markov Models, using a representation theorem :
Given the definition of a causal state as $\mathbb{P}[future|A] = \mathbb{P}[future|B]$, the partition of system states induced by the corresponding equivalence relations Recurrent Network is then enough to determine next state of the system, as it is a *deterministic* function of previous state and hidden states :

$$(x_{t+1}, s_{t+1}) = F\left[(x_t, s_t)\right]$$

$\rightarrow$ *Estimation of Hidden States and of the Recurrent Function thus captures entirely dynamical patterns of the system, i.e. full information on its dynamics and internal processes.*

Some questions for an application to Geography :

- Can the stationarity assumption be tackled through augmentation of system states ?
- Can heterogeneous and asynchronous data be used to bootstrap long time-series necessary for a correct estimation of the neural network ?

Next steps (until February 15th 2016)

- Theory exemplification, paper finalization [1w]
- Spatial Econometrics / Case study [0.5w]
- Cybergeo [0.5w]
- Wrap everything within a 1-year Memoire [1w]
